

Dotify

Music as shared presence.

A decentralized cultural social hub where a room is as easy to join as a link — while artists keep control of access, rights and value flows.

- Live shared listening
- Artist-owned runtimes
- Running on Polkadot Product DevNet

dotify-test01.dot

Streaming scaled access. It did not rebuild the commons.

Music has always organized presence — around a radio, a club, a street, a family.

Today, discovery is abundant but solitary. Artists still reach listeners through platforms they do not govern, while access, rights and value live in separate systems.

Dotify uses the room — not the feed — as the primary unit of discovery.

One room • two people • one shared moment

A working testnet slice now connects catalog, rooms and access.

Browse five registered releases

Free and protected tracks share one honest catalog.

Open a room and share one link

Guests listen without a wallet checkpoint.

See the split before unlocking

Runtime policy gates the source and routes support.

Protected room playback is host-based: listeners receive the ephemeral stream, never the encrypted source key.

Artists do more than upload. They claim a release space.

The artist path is part of the product, not a back-office afterthought.

One artist space per wallet

The owner controls the catalog and the runtime that applies release policy.

Context stays attached

Artwork, metadata, listening rule, price and royalty recipients travel with the release.

The social catalog starts here

A release enters shared rooms, not just a personal library.

Artist sovereignty is the system boundary, not a slogan.

The interface stays familiar; the rules live with the release.

Product distribution

Bulletin + DotNS publish dotify-test01.dot.

Operational services

The API controls keys; signaling coordinates rooms, not audio.

Room doctrine

Only the host needs protected-track access; guests keep link-first entry.

Product DevNet is an adaptive host, not a new dependency.

Standalone web remains the first public path; Product capabilities enhance it when the host exposes them.

Live now

- dotify-test01.dot via Bulletin + DotNS
- Explicit app-scoped Product identity
- Product-signed key and session requests

Being proven

- Host-signed contract writes through the Product CDM adapter
- Native mobile room audio when the host exposes WebRTC

The next milestone is a trustworthy public room — not more features.

01 Production evidence

Validate fast first sound across real browsers and gateways; harden room reconnect, TURN and mobile behavior.

02 Product-native value flow

Capture host-signed Classic unlock evidence, verify runtime readback, then design an explicit CASH ↔ runtime receipt model.

03 Human-free access

Bind Humanity / Individuality proofs to the listening identity before enabling a privacy-preserving personhood policy.

The goal is not another streaming app. It is music as shared social infrastructure, with artists in control.
